

Photomicrograph Rock Images Classification with Convolutional Neural Networks

Francesco Saccomando Ciaramella

April 4, 2023

Abstract: Several attempts were carried out to check if a small CNN model, based on the LeNet-5 model could classify rock images. 239 rock thin-section images including three rock types "metamorphic", "sedimentary", "volcanic" were selected from a dataset, which contained 2568 images, found on an online science database (Science Data Bank). The model has been trained and validated. After that the performances were evaluated with Accuracy, Loss, Confusion Matrix and "Accuracy per Fold". The model revealed a good performance notwithstanding the database shortness.

1 Introduction

Rock type classification is really important in geology and all his applications, the actual main way to classify is to use tools such as magnifying glass etc. This way of classification is time-consuming and costly so a Convolutional Neural Network (CNN) based approach could be the solution. CNNs have big advantages in image processing fields, in fact, they are widely used in image classification problems. This kind of method has been widely used in early years for the classification of rocks.[1] In this report I used a CNN to classify a photomicrograph rock images dataset acquired from Nanjing University of China, containing 3 rock classes : metamorphic, volcanic and sedimentary. In the 2 Section introduces Dataset details and CNN architecture. The 3 Section includes the model results and performances. Lastly the 4 Section contains an overall about the model and how it could be improved.

2 Methods

2.1 Dataset

The dataset used is a photomicrograph rock dataset acquired from Nanjing University of China [2] that includes three rock types: metamorphic, sedimentary, and volcanic rocks. From the original 2634 microscopic images contained, 239 have been selected, Table 1 shows the images distribution.

Metamorphic	Sedimentary	Volcanic
76	87	76

Table 1: Description of the Dataset

2.2 Model Architecture

I took inspiration from the LeNet-5 Architecture, invented by Yann LeCun in 1998. The structure forseees an initial Conv2D Layer (16, 4, activation='relu') followed by a Max Pooling2D Layer, another Conv2D Layer (7, 4, activation='relu') followed by a Pooling2D Layer. Finally a Flatten Layer followed by a Dense Layer (100, activation='relu') and the last Dense Layer (3, activation='softmax').

2.3 Environment and Training

I used Tensorflow as deep learning framework. The total 239 images were divided into training and testing datasets: 210 for training(and validation) and 29 for test. The input image had a 384x306 resolution (resized from the initial 1280x1024, using os and cv packages), the number of training epochs was 100, an early stopping callback with the following parameters was used:(monitor='valaccuracy',patience=10, mode="auto") to stop the training when the validation accuracy dropped. K-Fold Cross Validation has been set to 3 folds As optimizer I choose Adam and loss function SparseCategoricalCrossentropy All the experiment was executed on Google Colab jupyter notebook, running Python 3 using the "base" resources: 12.7GB RAM, 15GB RAM GPU(used for acceleration).

3 Results

The performance of the model has been compared using an accuracy vs validation accuracy graph(Figure 1), a loss vs validation loss graph (Figure 2),a confusion matrix(Figure 3) and with "score per fold"(Figure 4)

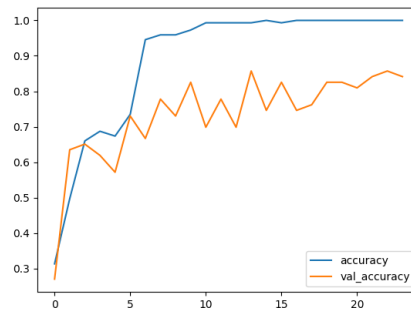

Figure 1: Accuracy.

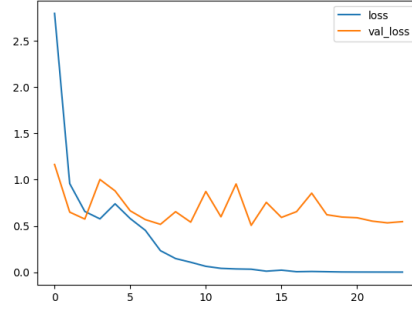

Figure 2: Loss.

As can be seen the validation accuracy remains stable at around 0.80, while the accuracy per fold got an average of 87%. The Confusion Matrix shows clearly that the the most common mispredicted label is between Metamorphic-Volcanic (labels 0-2) & Volcanic-Metamorphic (labels 2-0), this could have been caused by the similarity between the thin rock section images.

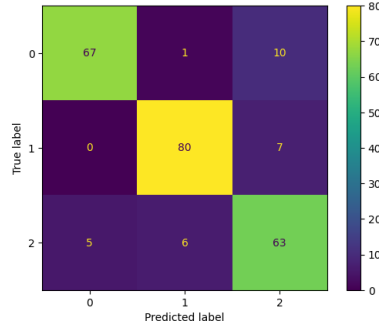

Figure 3: Confusion Matrix: Label 0 corresponds to "Metamorphic", 1 to "Sedimentary", 2 to "Volcanic".

```
Score per fold
-----
> Fold 1 - Loss: 1.61591374874115 - Accuracy: 88.7499988079071%
-----
> Fold 2 - Loss: 0.5691907405853271 - Accuracy: 81.25%
-----
> Fold 3 - Loss: 0.19602708518505096 - Accuracy: 91.13923907279968%
-----
Average scores for all folds:
> Accuracy: 87.04641262690227 (+- 4.21314741943439)
> Loss: 0.793710524837176
-----
```

Figure 4: Accuracy per Fold

4 Conclusions

CNNs models are an excellent tool for photomicrograph rock images classifications, the 80% average of accuracy despite the small amount of images in the dataset (reduced due to low computing power available) is a good start. Next step to improve performances could surely be the enlargement of the dataset, and the enhancement of the computational power provided to the CNN.
